### Agile Development

Agile development is just what it sounds like. This type of development focuses on evolution throughout the entire developmental process. It is ready for rapid changes through collaborative efforts of the entire team. They have a very adaptive planning process and is very flexible to any changes or problems that come up on the way. The software development process uses a lifecycle approach where each step is laid out and does not change very much. This method allows for the most efficient process when the end result is very clear and specific, but lacks in the department of diversity. For me, I would prefer to use the agile method if I had to pick one or the other. However, I am a very organized person and like things to be somewhat laid out so the best process for me would be one that combines the best aspects of both of these developmental processes.
